

Investment Portfolio – Documentation

\$500,000 portfolio, 12 stocks, Information Technology & Healthcare, Jan 2020 – Jan 2025

How the Stocks Were Chosen

I picked 12 stocks across two sectors to meet the diversification rules: Information Technology (4 industries, 2 companies each) and Healthcare (2 industries, 2 companies each).

- Software—Infrastructure: Microsoft (MSFT), Oracle (ORCL)
- Semiconductors: NVIDIA (NVDA), Advanced Micro Devices (AMD)
- Software—Application: Salesforce (CRM), Adobe (ADBE)
- IT Services: Accenture (ACN), IBM (IBM)
- Drug Manufacturers—General: Johnson & Johnson (JNJ), Pfizer (PFE)
- Healthcare Plans: UnitedHealth Group (UNH), Cigna (CI)

Weights range from 4% to 14% per stock, so everything stays inside the 3–20% band. Information Technology is 61% of the portfolio and Healthcare is 35%, both above the 30% sector minimum, and cash is 4% (under the 5% cap).

Data Sources & Logic

Historical purchase and sell prices came from Yahoo Finance historical closing-price data (looked up through StatMuse). Jan 20, 2020 is Martin Luther King Jr. Day, so the market was closed — I used the next trading day, Jan 21, 2020, for the purchase price. Jan 24, 2025 was a normal trading day, so no adjustment was needed there.

For live prices, Column L on the Portfolio sheet uses `VLOOKUP(Ticker, LivePrices!$A$4:$B$15, 2, FALSE)` to pull from the LivePrices sheet. I filled that sheet with current quotes for each ticker; in Excel with an internet connection, the same sheet can instead be kept live by selecting the Ticker column, setting its Data Type to Stocks, inserting the Price field, and refreshing with Data > Refresh All — the VLOOKUP on the Portfolio sheet doesn't need to change either way.

Calculation Breakdown

Everything except the raw inputs (ticker, sector, industry, description, weight, and the two sourced prices) is a formula:

- Shares Bought = $\text{ROUND}(\text{Investment Amount} / \text{Purchase Price}, 0)$
- Purchase Value = $\text{Purchase Price} \times \text{Shares Bought}$
- Value of Sold/Unsold Shares = $0.5 \times \text{Shares} \times \text{Sell Price (or Live Price)}$
- Transaction Fee = tiered IF() on share count
- Net Gain = $(\text{Sold Value} + \text{Unsold Value}) - (\text{Purchase Value} + \text{Fee})$

- $\text{Tax} = \text{MAX}(0, 15\% \times (\text{Sold Value} - 0.5 \times \text{Purchase Value}))$ — floored at zero
- $\% \text{ Gain Before/After Tax} = \text{Net Gain} / \text{Purchase Value}$, and $(\text{Net Gain} - \text{Tax}) / \text{Purchase Value}$

The Industry Pivot and Sector Pivot sheets group the same data with SUMIFS/AVERAGEIFS. The Portfolio data also sits in a proper Excel Table (PortfolioData), so a native PivotTable can be inserted from it directly if you'd rather have the actual PivotTable object.

Key Findings

Total purchase value across all 12 positions was \$480,269 (96% of the \$500,000, with 4% left in cash). Combining the 50% sold at the Jan 2025 price and the 50% still held at the live price, net gain after fees comes to about \$2.60M, with roughly \$145,660 owed in tax on the realized half. That's a 541.6% gain before tax and 511.3% after tax.

NVIDIA is the story here — its split-adjusted price went from about \$6 in Jan 2020 to over \$225 now, so it alone drives most of the portfolio's return even though it's only 14% of the money invested. Semiconductors as an industry averaged roughly a 1,760% gain; nothing else came close. Only two positions lost money — Adobe and Pfizer — and both losses are small, under 5%.

Rebalancing Insights

For the 3-year rebalance, I ranked all 12 stocks by return since purchase as of Jan 24, 2023, sold the bottom 6 (CRM, ADBE, ACN, IBM, JNJ, PFE), and split the \$218,203 in proceeds evenly into the top 6 (NVDA, UNH, ORCL, CI, MSFT, AMD). Holding that reallocated portfolio to Jan 24, 2025 was worth \$2,698,548, versus \$2,418,869 if nothing had been rebalanced — about \$279,679 (11.6%) better.

Basically all of that improvement comes from buying more NVDA at the 2023 checkpoint, since it was already the best performer and kept outperforming through 2025. That's the risk with a momentum-style rebalance like this one: it works well when the winner keeps winning, but it would have looked worse than a more diversified rebalance if NVDA had reversed instead.
